

Module: Problem 2

This module defines a single utility function that returns a constant integer value. The implementation does not depend on the input argument, making the function behave identically for any provided value.

Functions

`f(x)`

Description:

Returns the integer `3` irrespective of the argument supplied. The function ignores its parameter and always produces the same constant output.

Parameters: - `x` (*Any*): The input value is accepted but not used in any computation. It can be of any type (e.g., `int`, `float`, `str`, etc.).

Returns:

`int` – the constant value `3`.

Examples:

```
# Based on observed runtime behavior
result = f(0)           # → 3
result = f(1)           # → 3
result = f(-1)          # → 3
result = f('test')     # → 3
result = f('')          # → 3
```

Edge Cases / Notes: - No crashes or exceptions were observed for any input type during testing. - The function's behavior is deterministic and does not depend on the value or type of `x`.
