

Module: `Problem 4 - Decrypt a Story`

This module provides a single utility function that attempts to decrypt an encoded story using the `CiphertextMessage` class. The function retrieves the encrypted story via `get_story_string()` and then invokes the decryption routine. It is intended to return the plaintext version of the story, but the current implementation lacks the necessary import/definition for `CiphertextMessage`, leading to a runtime error.

Functions

`decrypt_story()`

Description:

Fetches the encrypted story string, wraps it in a `CiphertextMessage` object, and returns the result of its `decrypt_message()` method, which should be the decrypted (readable) story.

Parameters:

- *None*

Returns:

- `str`: The decrypted story text (expected when the required `CiphertextMessage` class is available).

Examples:

```
# Based on observed runtime behavior
result = decrypt_story() # → NameError: name 'CiphertextMessage' is not defined
```

Edge Cases / Notes: - **Crash observed:** The function raises a `NameError` because `CiphertextMessage` is not defined or imported in the module. To use this function successfully, ensure that the `CiphertextMessage` class (typically from the `caesar` or `crypto` module) is properly imported. - The function also depends on a `get_story_string()` callable that returns the ciphertext; this must be defined elsewhere in the codebase.
