

Module: Problem 5

This module provides a simple utility function for removing all vowel characters from a given string while preserving the original order of the remaining characters. The resulting string is printed to standard output; the function does not return a value.

Functions

`print_without_vowels(s)`

Description:

Creates a version of the input string `s` that contains no vowel characters (`a, e, i, o, u` in either lower- or upper-case). The characters that remain retain their original order. The function prints this vowel-free string and returns `None`.

Parameters: - `s` (*str*): The source string from which vowels will be removed.

Returns:

`None` – the function prints the processed string but does not return it.

Examples:

```
# Based on observed runtime behavior
result = print_without_vowels('hello') # → None (prints "hll")
result = print_without_vowels('test')  # → None (prints "tst")
result = print_without_vowels('')      # → None (prints "")
result = print_without_vowels('abcde') # → None (prints "bcd")
```

Edge Cases / Notes: - The function handles empty strings gracefully, printing nothing and returning `None`. - Vowel removal is case-insensitive; both uppercase and lowercase vowels are omitted. - The function does **not** raise exceptions for any string input; it always returns `None`.
