

Module: `Problem 1 - Word Scores`

This module provides utilities for calculating Scrabble-style scores for words.

The primary function, `getWordScore`, computes a word's score based on individual letter values, the word length, and an optional bonus when the word uses all tiles from a hand of size `n`. The module expects a global dictionary `SCRABBLE_LETTER_VALUES` that maps lowercase letters to their Scrabble point values.

Functions

`getWordScore(word, n)`

Description

Calculates the total score for a given `word`. The score is the sum of the Scrabble values of each letter, multiplied by the number of letters used, and adds a 50-point bonus if the word consumes exactly `n` letters (i.e., the entire hand). The function assumes that `word` consists only of lowercase alphabetic characters and that `n` is a non-negative integer representing the hand size.

Parameters - `word` (*str*): The word whose score is to be computed. Must contain only lowercase letters. - `n` (*int*): The size of the hand (number of tiles originally available).
Used to determine whether the 50-point bonus applies.

Returns

`int` – The computed score (always ≥ 0). Returns `0` immediately if `word` is empty.

Examples

```
# Example 1: empty word (any hand size, even negative)
result = getWordScore('', -1)    # → 0

# The following examples raise NameError because SCRABBLE_LETTER_VALUES
# is not defined in the current context. They illustrate the expected
# behavior once the dictionary is provided.

# result = getWordScore('hello', 0)    # → NameError: name 'SCRABBLE_LETTER_VALUES' is not defined
# result = getWordScore('test', 1)     # → NameError: name 'SCRABBLE_LETTER_VALUES' is not defined
# result = getWordScore('a', 10)       # → NameError: name 'SCRABBLE_LETTER_VALUES' is not defined
```

Edge Cases / Notes - **Empty word**: Returns `0` without consulting `SCRABBLE_LETTER_VALUES`. - **Missing**

`SCRABBLE_LETTER_VALUES`: If the global dictionary is not defined, the function raises a `NameError`. Ensure that the mapping is imported or defined before calling the function. - **Bonus condition**: The 50-point bonus is applied

only when the number of letters used (`len(word)`) exactly equals `n`. If `n` is negative or zero, the bonus will never be awarded (unless `len(word)` is also zero, which is handled earlier). - **Input validation**: The function does **not** validate that `word` contains only valid letters; passing an invalid character will also raise a `KeyError` from the missing entry in `SCRABBLE_LETTER_VALUES`.
