

Module: **Problem 2**

This module defines a single utility function that always returns the integer `3`, irrespective of the argument supplied. It can be used wherever a constant value of `3` is required without performing any computation on the input.

Functions

`f(x)`

Description: Returns the constant integer `3` for any provided argument. The input is ignored, making the function effectively a constant generator.

Parameters: - `x` (*Any*): The value passed to the function. Its type is not used in the computation; examples include integers, strings, or any other Python object.

Returns: `int` — always the value `3`.

Examples:

```
# Based on observed runtime behavior
result = f(0)           # → 3
result = f(1)           # → 3
result = f(-1)          # → 3
result = f('test')     # → 3
result = f('')          # → 3
```

Edge Cases / Notes: - The function does not raise exceptions for any input type; it consistently returns `3`.
